

AVIATION ACCIDENT ANALYSIS USING TABLEAU

NAME: Anusha Manjappa

CIN: 305851746

CIS5270 Project1:

Aviation Accident Analysis

(2012-2016)

A) Dataset URL's:

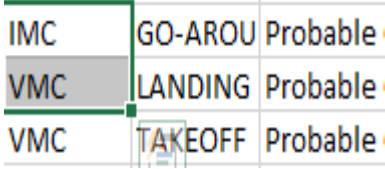

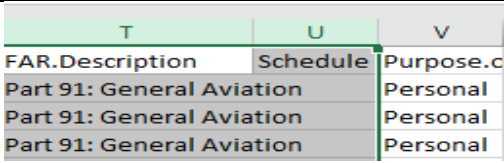

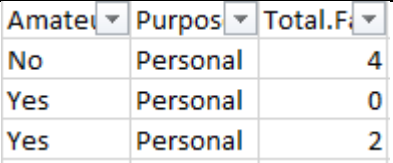

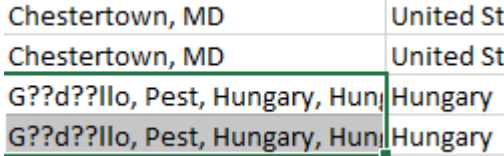

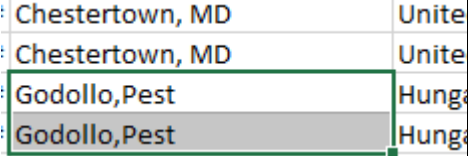

<https://www.kaggle.com/khsamaha/aviation-accident-database-synopses>

<http://www.nts.gov/investigations/data>

The dataset contains information from 1962 and later about civil aviation accidents and selected incidents within the United States, its territories and possessions, and in international waters. The data accumulated in the NTSB (National Transportation Safety Board) database about aviation accident provides a platform to investigate the various details of the accidents like injury severity, aircraft damage, total fatal injuries, total serious injuries, total minor injuries, the exact location n where it occurred, the weather conditions that prevailed then, etc. Due to this huge data volume and to concentrate more on the most recent incidents, I have selected a part of the dataset to analyze the incidents that have occurred from the year 2012-2016. On the whole I, have considered 24 columns and 6213 rows for my analysis for the years 2012-2016.

B) Data Cleaning:

| Scope/Problem | Dirty Data | Cleaned Data/ Remarks | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

[Tools used: Calculated fields, Dates, Totals]

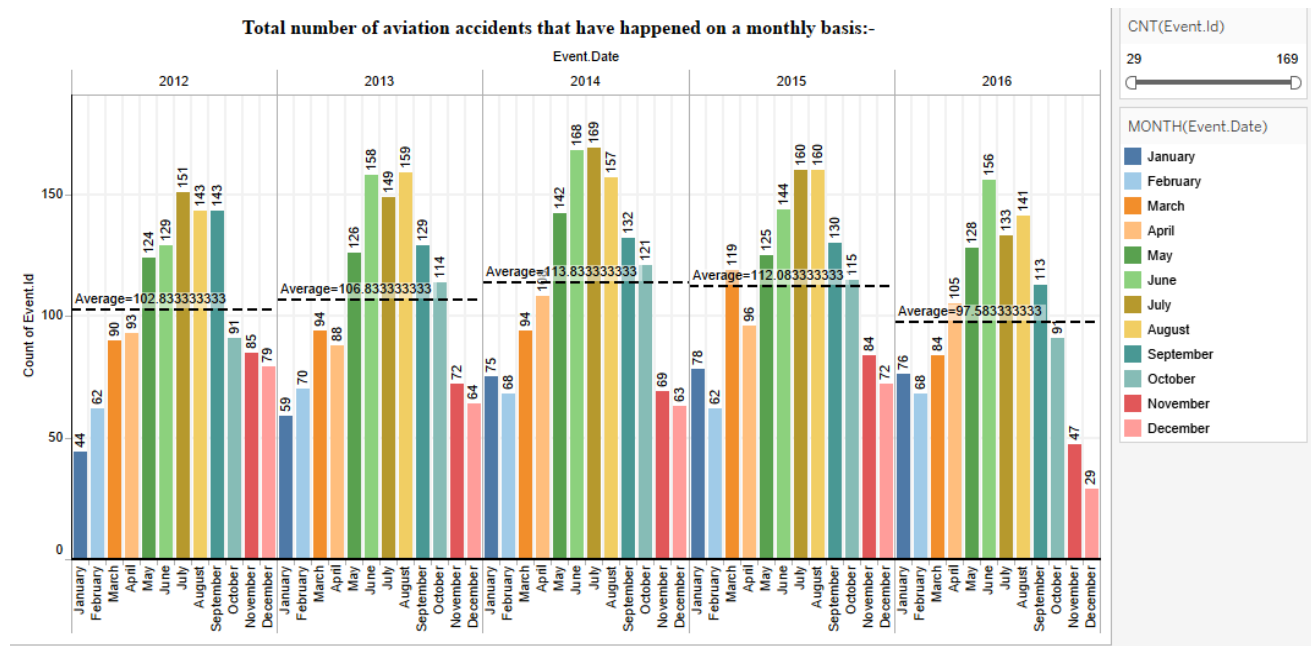

The above text tables depict the following measures for each month of the years from 2012-2016.

- Total Number of Fatal Injuries
- Total Number of Minor Injuries
- Total Number of Serious Injuries

This helps us know the severity of each incident that has occurred. It also consists of the count of the total number of accidents happened in each month of all the years from 2012-2016 and the total number of accidents per year. The total number of accidents per year has been calculated with the help of a calculated field, Number Of Events= COUNT ([Event.Id]). This returns the count

of event ids which is a unique attribute on a monthly basis and totals it to get the number of accidents per year.

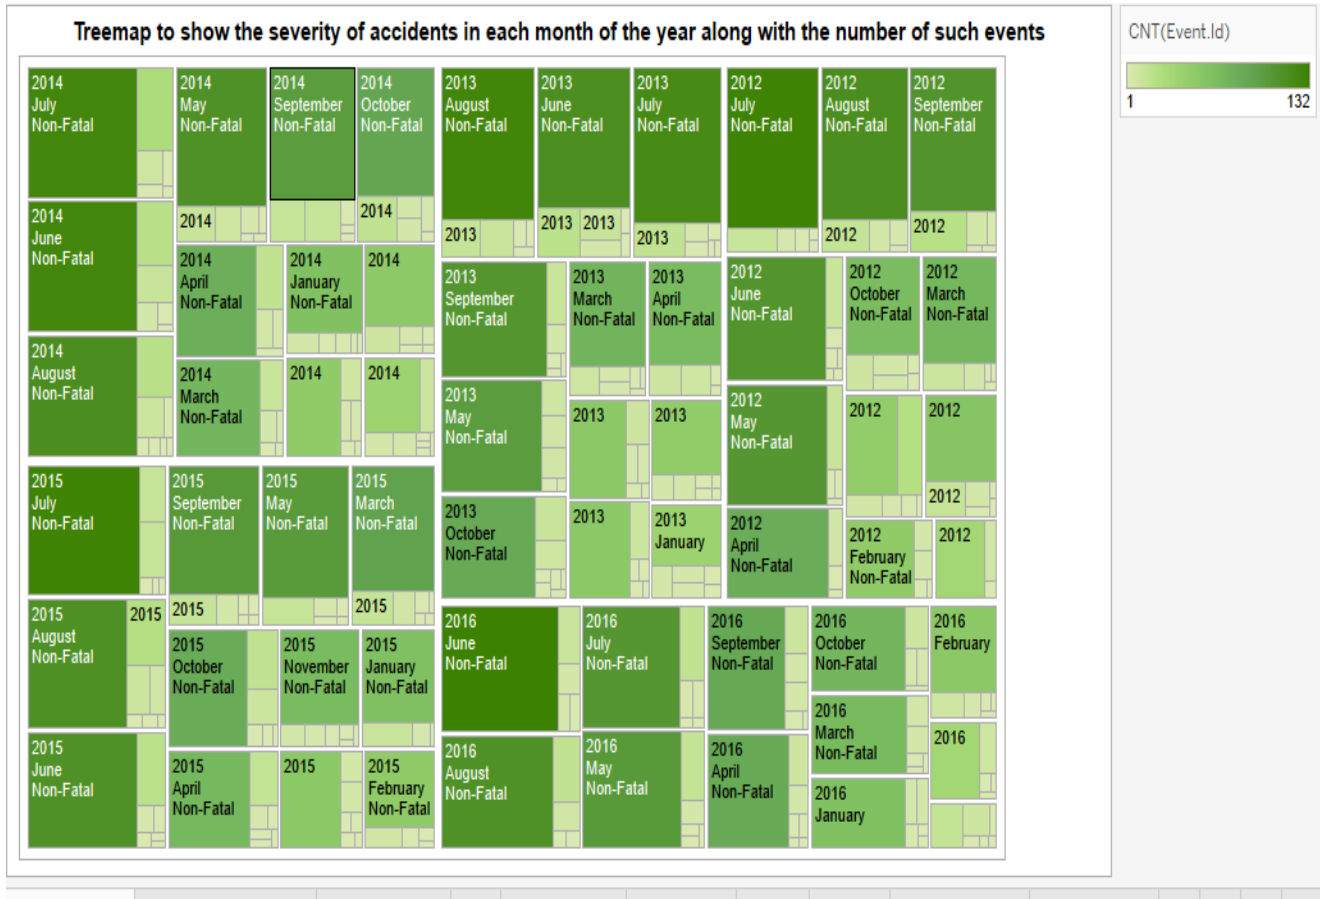

- 2) **Analysis of total number of aviation accidents that have happened on every month of the considered years and the average of the number of accidents per year.**

[Tools used: Calculated fields, Dates, Reference Line]

The above analysis using a side-by-side bar chart shows the count of the total number of aviation accidents that have happened per month of all the years considered with the help of a calculated field, `Number_Of_Events= COUNT ([Event.Id])`. The different months are all displayed in different colors as shown in the filter label. The average of the number of events per year has also been displayed using the reference line to have a rough idea about the number accidents happening. The average number of accidents was the highest in 2014 and lowest in 2016 which says that there is a considerable decrease in the number of accidents. It can also be seen that the lowest number of accidents was in Dec 2016 where there were just 29 accidents and the highest was in July 2014 where there were 169 incidents which were reported.

- 3) **Analysis of total number of aviation accidents that have happened on every month of the considered years and the average of the number of accidents per year.**

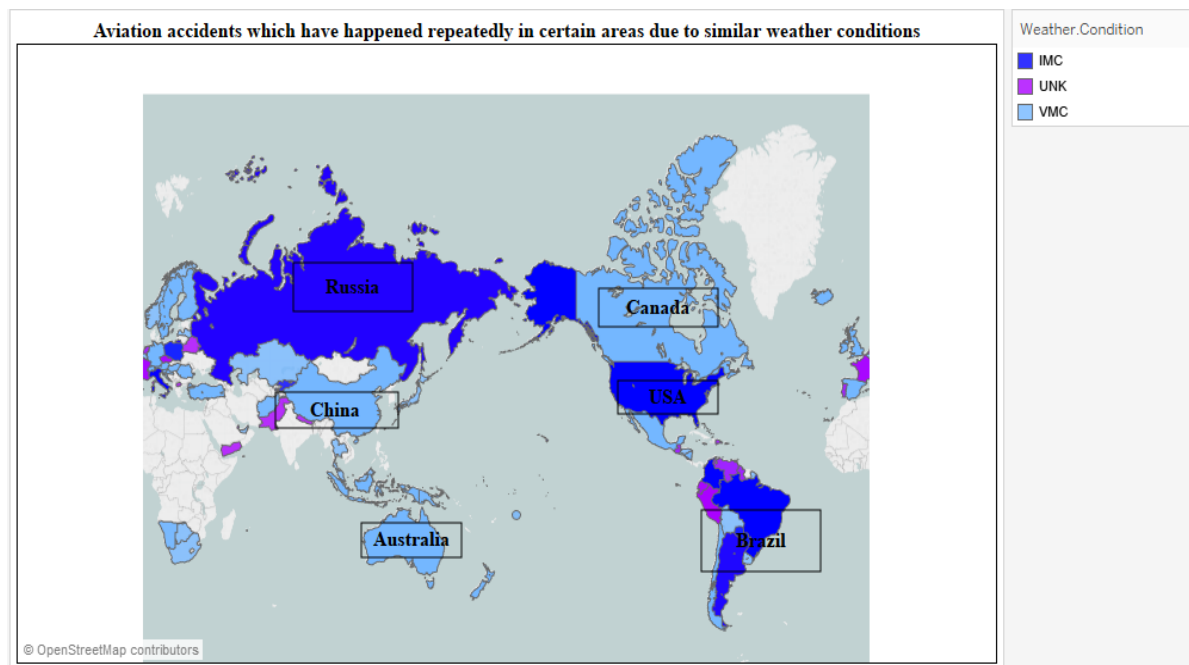

[Tools used: Calculated fields, Dates, Tree Maps]

I have demonstrated the severity of each incident in the form of a tree map here. The ones in dark color are the non-fatal accidents. The color goes lighter as the fatality increases. I have also demonstrated the number of such events that have occurred and that can be distinguished by the size of the blocks in the tree-map. More the number of incidents, bigger is the block of the tree-map. I have also labeled the respective years on them to make it more understandable. The number

of such events that have occurred is again calculated by a calculated field which counts the number of such events. This helps us analyze the severity of the incidents and to see if they have reduced over time.

4) Which are the aviation accidents which have happened repeatedly in certain areas due to similar weather conditions?

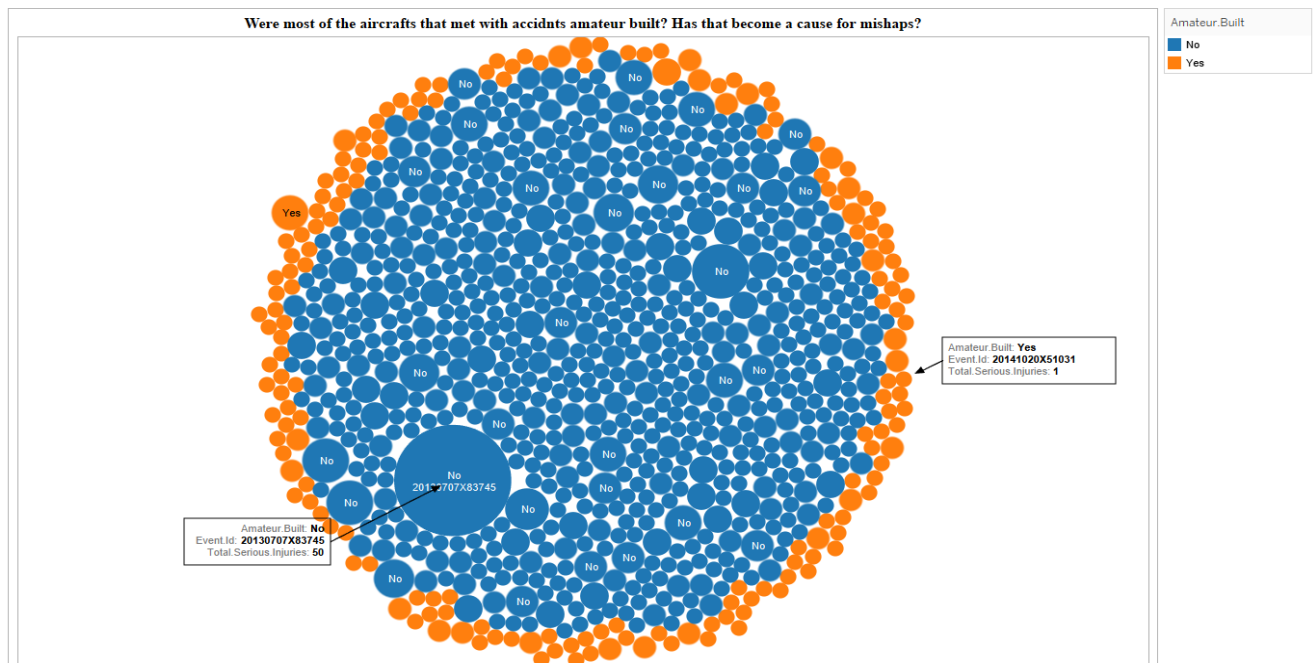

[Tools used: Geographic map]

This visualization illustrates the areas where accidents have happened due to similar weather conditions. As seen in the area in and around Russia, US, Brazil and Argentina the failure of the aircraft was mainly due to the weather condition of IMC, this describes the weather conditions that require pilots to fly primarily by reference to instruments, and therefore under Instrument Flight Rules (IFR), rather than by outside visual references under Visual Flight Rules (VFR). Therefore, pilots must be more careful in such situations as they do not have outside visual references. In areas like Canada, Australia and China accidents have occurred mostly in the weather condition

of VMC. It also describes the severity of accidents which is found to be fatal as pointed out in the diagram. The weather conditions are displayed in different colors for a better understanding.

5) **Were most of the aircrafts that met with accidents amateur built? Is it a huge number when compared to the aircrafts that were not amateur built? Has that become a cause for mishaps?**

a) Packed Bubble Chart

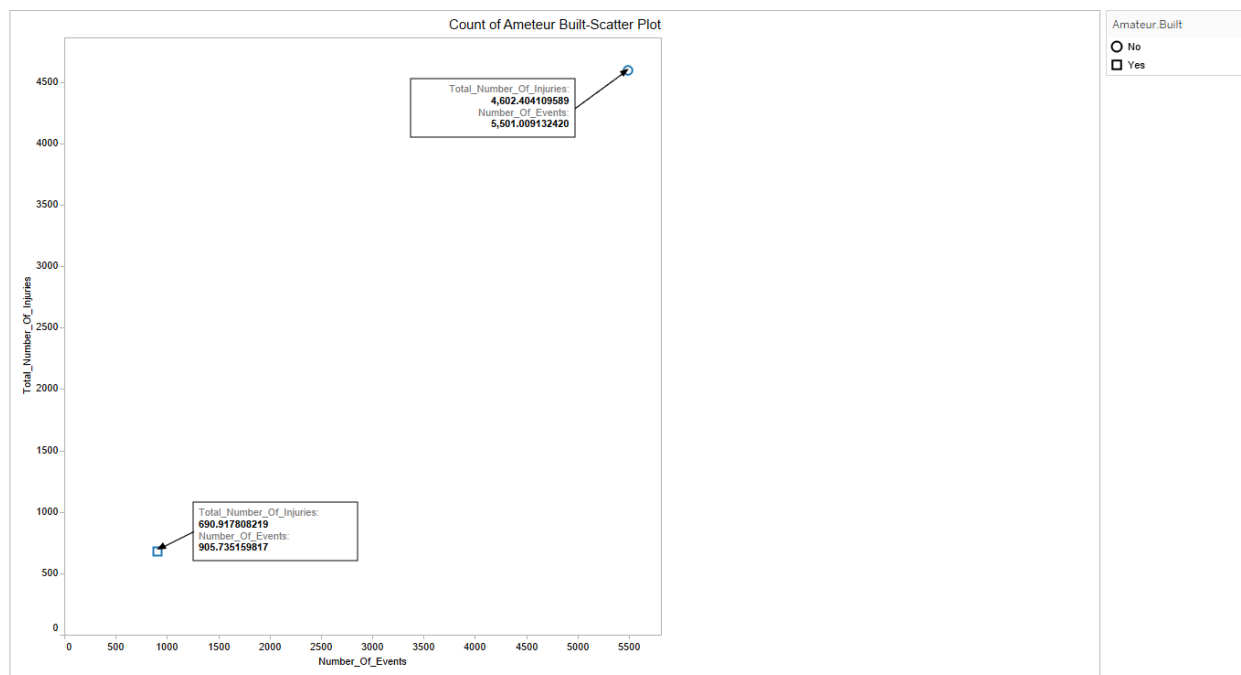

[Tools used: Packed Bubbles Chart]

Amateur-built aircraft can be built from scratch, based on original or established designs, or from a kit. If a kit is used, the builder must have completed most of the build for it to be considered an amateur-built aircraft. Experimental and amateur-built aircraft include any aircraft that is fabricated and assembled by anyone for their own education and/or recreation. During the analysis process, it was found that the number of amateur built aircrafts that failed were very less in number

as shown in the figure. The ones shown in orange are all failures of amateur built aircrafts and the ones in blue were not built by amateurs. Along with the separate colors used, I have also labeled the total number of serious injuries that occurred due to that mishap. The sizes of the bubbles vary per number of serious mishaps that have occurred. As seen, I have pin-pointed the smallest and biggest bubble which indicate 1 serious injury and 50 serious injuries respectively. Thus, it can be inferred that organizations are taking good protective measures about the amateur built aircrafts and that is not a reason for the accidents that have occurred.

b) Scatter Plot Chart

[Tools used: Scatter Plot, Calculated Fields]

In addition to the above bubble chart this above visualization uses two calculated fields, Number_Of_Events and Total_Number_Of_Injuries in a scatter plot to find out the exact count of accidents by amateur built aircrafts which is 905 and the total number of injuries which is 609. This is a very small amount in comparison to the accidents and injuries of the non-amateur built

aircrafts which is 5501 and 4602 respectively. Therefore, once again we can infer that it has not been a cause for the huge number of mishaps.

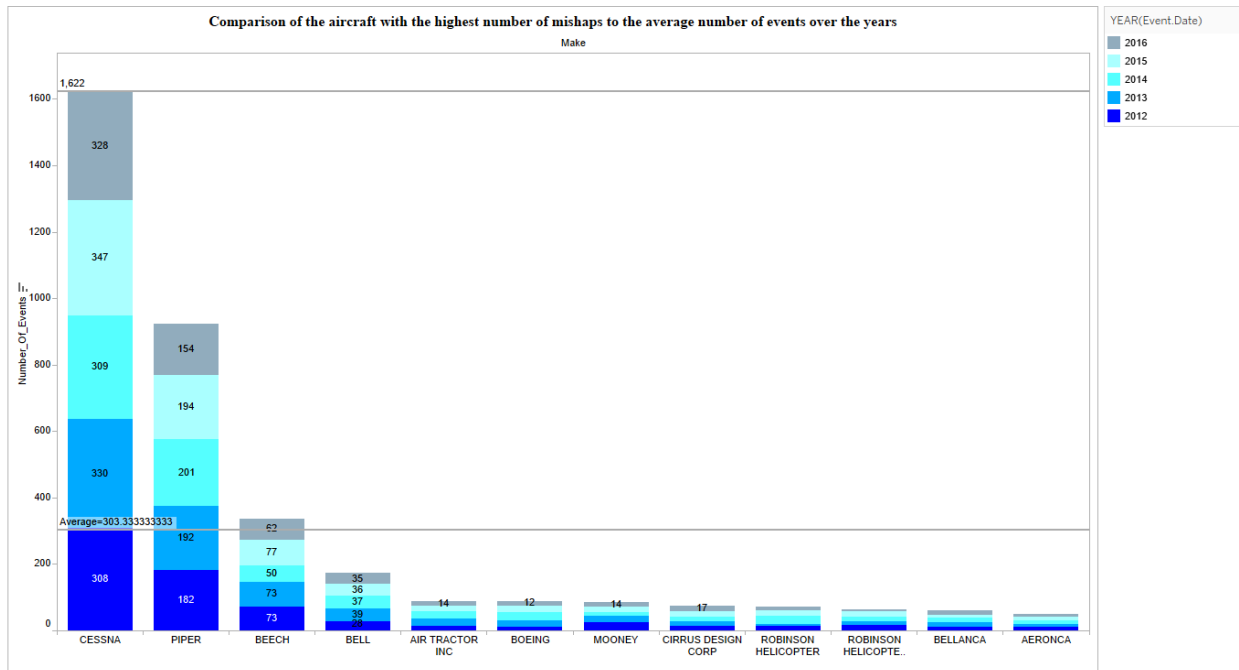

6) Which airline has experienced the most number of failures? Which are the top most airlines going through many failures?

[Tools used: Calculated Fields, Rank]

This Visualization shows the Top airline makes which have accounted for maximum number of airline disasters. I have set a filter to get the Airline makes who have accounted to about 50 and above accidents and ranked. The aircraft maker CESSNA has had a total of 1622 mishaps in the last 5 years itself and it has been highlighted in the above visualization. Next is the line is PIPER with a total number of 923 accidents. I have used a calculated field Number_of_Events to calculate the number of accidents per aircraft make. This clearly explains the aircraft make to be chosen and not chosen in the future.

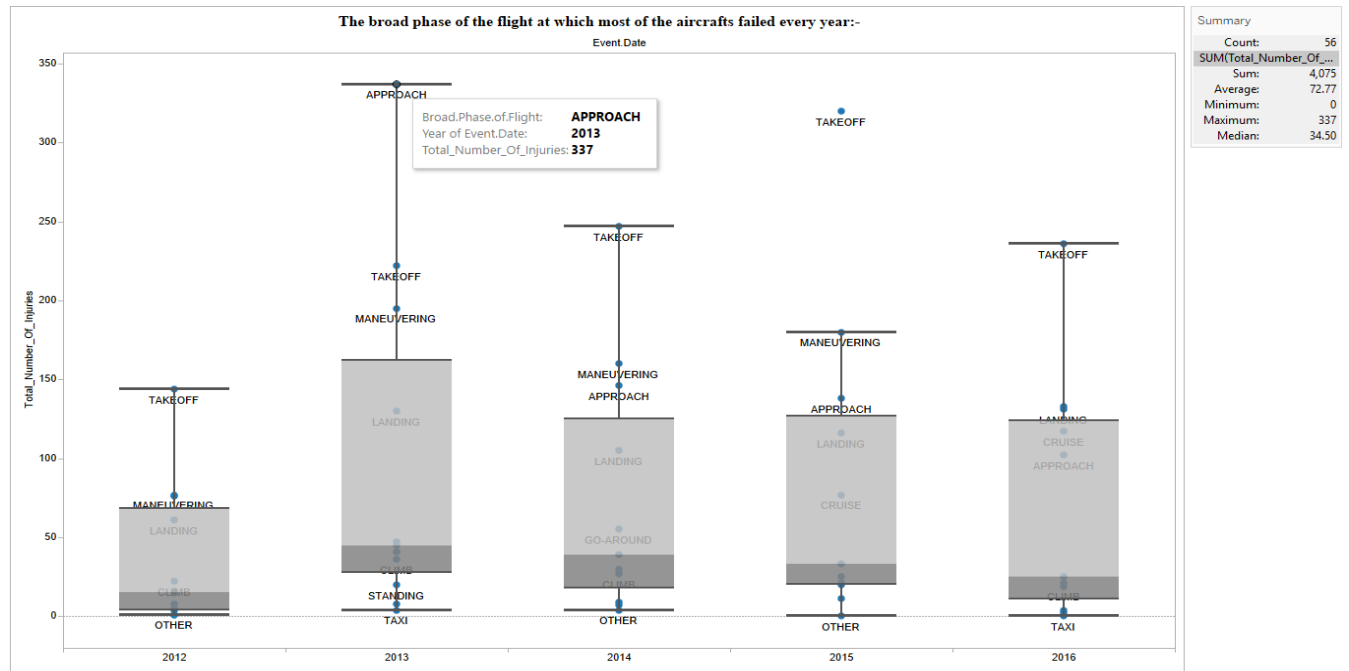

7) Comparison of the aircrafts with the highest number of mishaps to the average number of events over the years

[Tools used: Calculated Fields, Dates, Reference Line]

In this Visualization, in addition to the Top airline makes which have accounted for maximum number of airline disasters, I have shown the year wise split up of the number of disasters with different colors for better analysis. The make CESSNA has experienced the most number of disasters which is a total of 1622 as shown by the reference line. This is now split up as 328 disasters in 2016, 347 in 2015, 309 in 2014, 330 in 2013 and 308 in 2012. Similar kind of break up has been shown for all other aircraft makes also. This has also been ordered in descending order for better understanding. A reference line indicates that the average number of mishaps for the last 5 years has been 303 and there are three aircraft makes who have experienced failures way beyond this value. Thus, measures can be taken to avoid these aircraft makers.

8) The broad phase of the flight at which most of the aircrafts failed every year.

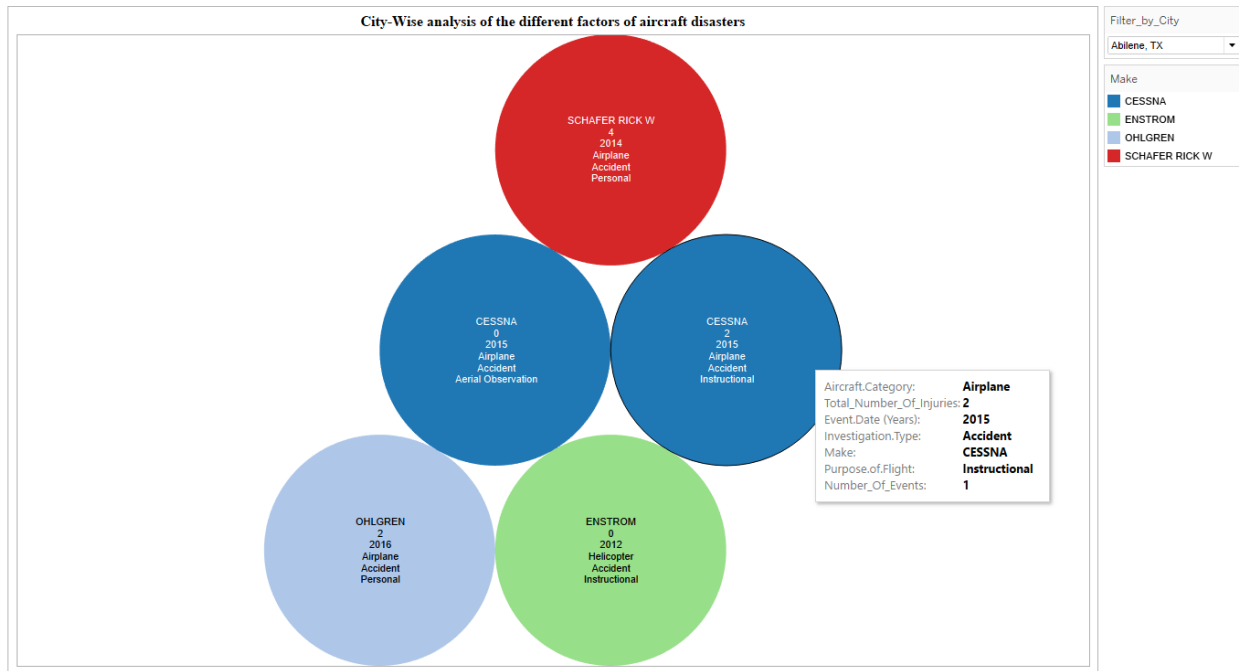

[Tools used: Calculated Fields, Dates, Box & Whisker plot]

Broad phase of flight refers to a period within a flight at which the accident happened. It helps them to investigate the cause of the accident and to see what should be done to avoid this in the future. As shown in the visualization, the highest number of injuries, i.e. 337 in the year 2013 have occurred at the “Approach” broad phase of the flight. The second highest in row with 320 injuries in the year 2015 stands the “Take off” broad phase of the flight. The total number of injuries has been got from a calculated field Total Number Of Injuries= [Total.Fatal.Injuries]+ [Total.Minor.Injuries]+ [Total.Serious.Injuries]. The boxplot is a convenient way of graphically depicting groups of the total injuries through their quartiles. The lines extending vertically from the boxes (whiskers) indicates variability outside the upper and lower quartiles. The bottom and top of the box are the first and third quartiles, and the band inside the box is the second quartile

(the median). The entire summary of every plot is listed out on the right in the summary plot when the cursor is pointed to the respective observation.

9) City-Wise analysis of the different factors of aircraft disasters.

[Tools used: Calculated Fields, Parameters, Packed Bubbles chart]

This Visualization shows City wise details of all the airplane disasters like Aircraft Category, Total Number of Injuries, Year of the Event, Investigation Type, Make of flight, Purpose of flight and number of accidents. All these fields are again grouped per the make of aircrafts and put in different colors. Calculated fields are used to calculate the total number of injuries and total number of accidents. I have created parameters Filter_By_City and Filter_For_Selecting_City to select the state and city we want to analyze. For instance, in the above visualization when pointed at one of

those blue bubbles, it says that an airplane made by CESSNA met with 1 accident in the year 2015 with one injury and the purpose of that flight was instructional.

10) A forecast on the number of injuries and total number of accidents in the upcoming years.

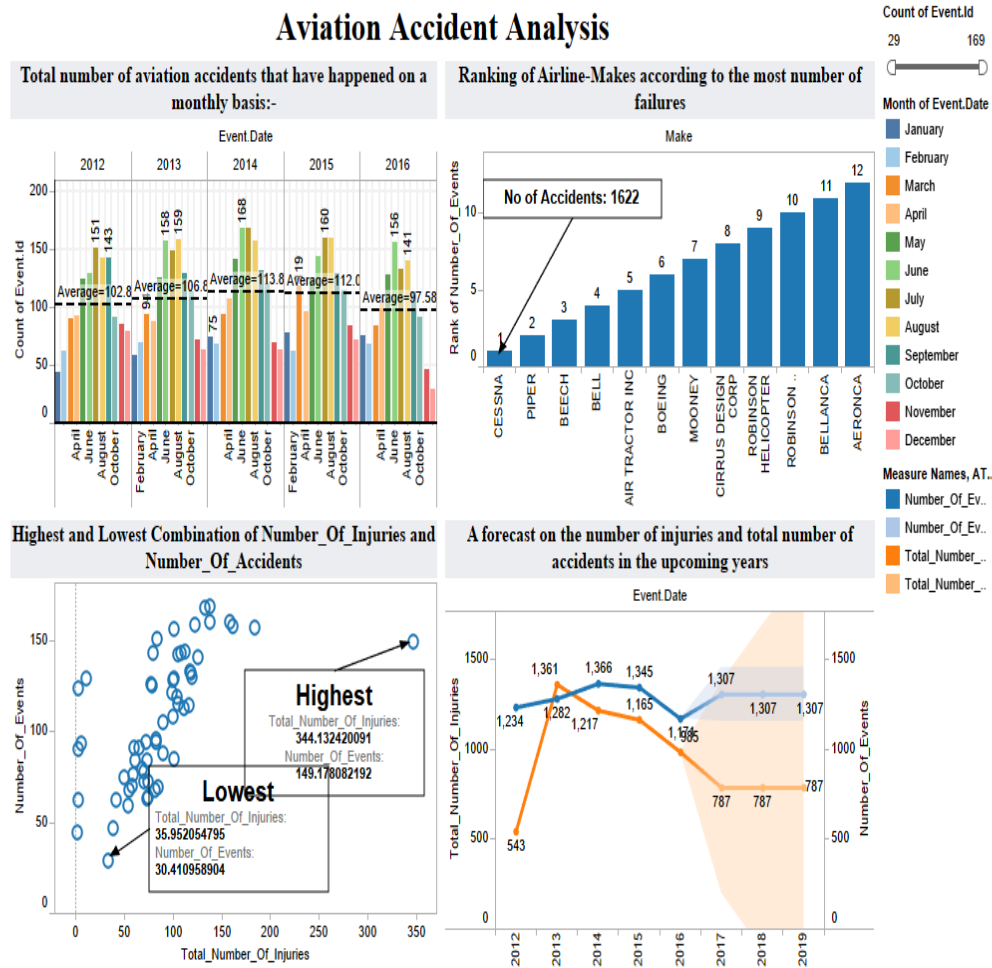

[Tools used: Calculated Fields, Dates, Forecast Trend Lines, Dual Axis Chart]

This Visualization shows the predicted values of the fields Total_Number_Of_Injuries and Total_Number_of_Accidents for the upcoming 3 years. The field Total_Number_Of_Injuries is a calculated field got by adding fields [Total.Fatal.Injuries], [Total.Minor.Injuries], [Total.Serious.Injuries]. The field Number_of_events which gives a count of all the accidents is also a calculated field got by the expression COUNT([Event.Id]). Total_Number_Of_Injuries field is on the left y-axis and is given in Orange. Number_of_events is on the Right y-axis and is given in Blue. The forecast lines show that the estimated number of flight accidents could be around 1307 overall which is slightly lesser than the number of accidents that have happened in the

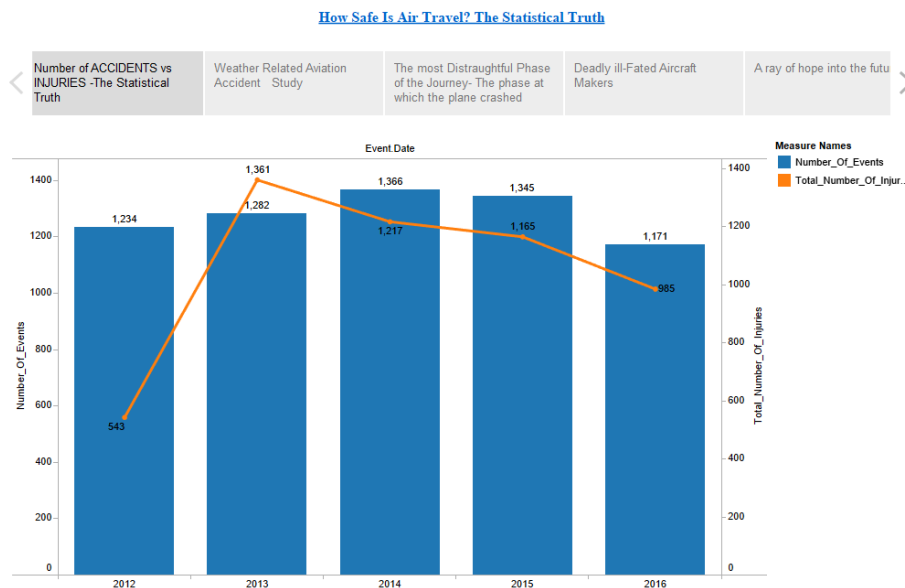

previous years. The number of injuries in the future years has been forecasted to be 787, which is reasonable when compared to the injuries happened in the past which was more than 1000 in most of the cases.

D) Dashboard:

E) Story telling:

Flights have been one of the most preferred ways of travel for long and short distances these days. When you can reach a place nearly 400 miles away in about roughly just 1.5 hours by flight while you would need about 12 hours by road, anyone would prefer the airways. It's easy to think of airplanes as a mode of transportation, but the aircraft itself is just one part of a wider air transportation system that includes airline operations, maintenance, crews, airports, security, weather services, and the air traffic control system. So, when we consider the safety of air travel, we must look separately at different countries and regions.

The number of fatalities attributed to air travel has been declining rapidly over the past years. Considering that the number of flights and passenger miles has increased nearly as quickly, the actual rate of fatalities continues to fall dramatically, by any measure. There are now approximately three times as many passenger miles flown as there were 30 years ago, but about one half the number of fatalities, on average [1].

According to the data from NTSB, there were 543 injuries from 1234 accidents in 2012 out of which 316 were minor injuries which shows that there were not many serious accidents this year although the count of accidents was high. 2013 produced 1361 injuries in 1282 accidents out of which there was a total of 485 fatal injuries, 549 minor and 327 serious injuries. 2014 had 1217 injuries worldwide from 1366 accidents where there was a total of 537 fatal injuries, 403 minor and 277 serious injuries. 2015 had 1165 injuries worldwide from 1345 accidents where there was a total of 537 fatal injuries, 403 minor and 277 serious injuries and the most recent 2016 had 985 injuries from 1171 accidents. So yes, 2014 was a bad year in terms of total accidents and total number of fatalities too. The last most fatal airline accident in the United States was Asiana Airlines Flight 214 which crashed in San Francisco on July 6, 2013. It resulted in three fatalities out of 307 passengers and crew on board. Prior to that, the last accident was the February 12, 2009 crash of Colgan Air Flight 3407 near Buffalo, New York, which resulted in the deaths of all 50 people on board [2].

Experts follow and determine what went wrong and work out how to prevent these horrific tragedies from happening again. They examine the wrecks and official records, and hear from eyewitnesses, passengers and aviation experts as they reconstruct some of the most tragic disasters in aviation history. Air Crash Investigation looks at what went wrong and how future disasters can be averted [3]. One of the most important factor they consider is the weather condition that prevailed during the accident. In aviation, a visual meteorological condition (or VMC) is an aviation flight category in which visual flight rules (VFR) flight is permitted—that is, conditions in which pilots have sufficient visibility to fly the aircraft maintaining visual separation from terrain and other aircraft. Whereas IMC describes weather conditions that require pilots to fly primarily by reference to instruments, and therefore under Instrument Flight Rules (IFR), rather

than by outside visual references under Visual Flight Rules (VFR) [4]. In countries like Russia, US, Brazil and Argentina the failure of the aircraft was mainly due to the weather condition of IMC, this describes the weather conditions that require pilots to fly primarily by reference to instruments, rather than by outside visual references under Visual Flight Rules (VFR). Therefore, pilots must be more careful in such situations as they do not have outside visual references. In countries like Canada, Australia and China accidents have occurred mostly in the weather condition of VMC.

Another important factor considered for investigation is the broad-phase-of-flight. The entire journey can be put into six phases, namely Taxi, takeoff, climb, cruise, descent and final approach/landing. Almost half of all accidents occur during the final approach and landing stages. Fatal accidents are also likely to occur during the climbing stage. If the aircraft left the gate with undetected faults, these may become apparent during the climb, as the first stage taking place off the ground, and could prove dangerous. Most accidents and fatalities take place during the departure (take off or climb) and arrival (approach or landing) stages. During these phases aircraft are close to the ground and in a more vulnerable configuration than during other flight phases. Accordingly, in the past 5 years, most of the fatal flight injuries have happened at the “Approach” phase of flight. We have a total of 337 fatal injuries accounted at this phase.

One important measure taken to avoid aviation accidents is to avoid the aircraft makers having the most number of mishaps or to make them improve their standards. In the past five years, it was found that the aircraft maker CESSNA has seen 1622 accidents. PIPER stands second with 923 accidents. With all these analysis, we have finally predicted the trend of the number of accidents and the number of injuries in the future years to come. There is a considerable decrease in the number of injuries to 787 injuries per year but the number of accidents hasn't seen much of

a dip in the count. With all these analysis, investigations and predictions hopefully better measures are taken to avoid airplane mishaps in the future. Flying is one of the safest forms of transport. But what happens when tragedy strikes? From human error and accidents to mechanical faults and design flaws, the success of aviation history is punctuated with disaster and catastrophe. It's rare, but it does happen.
